According to the Copper Alliance, important advantages of round tube plate fin (RTPF) coils are ease of cleaning and good condensate drainage. The "plate fins" of RTPF coils typically are oriented vertically so water drains easily from the top to the bottom of the sheets. The tubes penetrate the sheets at right angles and water easily flows around them. The same holds true for RTPF coils made from smaller diameter copper tubes. There may be more tubes penetrating the plate fins but water flows easily around the smaller diameter tubes.

Airside heat transfer around smaller diameter tubes now can be modeled with unprecedented accuracy. Research supported by the International Copper Association (ICA) and conducted by Optimized Thermal Systems, Inc. (OTS) compares the performance of slit fins and louvre fins for smaller diameter (3 mm to 5 mm) copper tubes.\(^1,2\)

Previously only the largest OEMs could afford to perform coil optimization through CFD modeling. Now, thanks to the Center for Environmental Energy Engineering (CEEE) at the University of Maryland and OTS, techniques for optimizing coil designs are available to users of CoilDesigner\(^\circledR\), a highly customizable software tool that allows designers to simulate and optimize the performance of heat exchangers.\(^3\)

OTS works with coil designers around the globe to optimize heat exchanger geometry, including the use of smaller diameter tubes. CoilDesigner includes the latest heat transfer and pressure drop models published in the open literature and users also can plug-in proprietary models. OEM users can shorten product development costs and quickly bring products to market.

**RESEARCH ON WAVY FINS**

A wavy fin is a plate fin with no holes and so it drains even better. Wavy fin designs have been found to be more effective for heat pumps where the outdoor evaporators may be subject to frosting; and for refrigeration equipment where frosting and condensation cancels the advantages of slit and louvre type fins due to the clogging of the openings. Also, enhanced fins such as slit or louvered fins aggravate the dust accumulation in the condensers of refrigerated display cabinets. Condensers in display cabinets are especially prone to dust accumulation because they are positioned close to the floor.

Supported in part by International Copper Association, researchers at the Institute of Refrigeration and Cryogenics, Shanghai Jiao Tong University, conducted research to examine the feasibility of replacing 9.52 mm copper tubes with 5 mm diameter tubes in the condensers of refrigerated display cabinets.\(^4\)

Wavy fins were chosen for this application because of considerations about dust accumulation. The fin structure was selected by theoretical analysis and the flow path of 5-mm diameter tube heat exchanger was analyzed using a heat exchanger simulation tool to find a suitable balance between heat transfer and pressure drop. The simulation results suggested that cost of the condenser could be reduced by 26 percent using the 5-mm tube with performance the same as the 9.52 mm prototype. The experimental data validated the simulation results, proving the feasibility of applying the small diameter tubes in display cabinets.

In related research, the CEEE investigated the design space for wavy fin heat exchangers having copper tube outer diameters ranging from 2 mm to 5 mm. They found that existing correlations were not applicable to the design space, thus justifying the need for new equations.\(^5,6\)

There is little doubt that the use of hydrofluorocarbons (HFCs) will be phased down. It is only a matter of how soon. Low refrigerant volumes are universally desirable because of the flammability of low-GWP refrigerants. One of the advantages of smaller diameter copper tubes is that they allow for a reduction in refrigerant volume.

Although classified according to ASHRAE 34 as Group A3 (flammable) refrigerant, R-290 is allowable for refrigeration and air-conditioning applications under certain conditions, according to rulings by the US EPA as well as regulatory agencies in other countries. Notwithstanding specific regulations under development, R-290 is expected to be an important eco-friendly refrigerant for the foreseeable future. Safety standards include such requirements as limiting the refrigerant mass per refrigerant loop, eliminating nearby sources of ignition and prohibiting the use of such equipment near points of egress.

The U.S. Environmental Protection Agency’s (EPA’s) Significant New Alternatives Policy (SNAP) program has proposed to list as acceptable, subject to restrictions, the use of propane in certain commercial refrigeration applications. 1

MicroGroove technology can help meet the regulatory requirements for R-290 because refrigerant volumes can be greatly reduced by using smaller-diameter copper tubes. Already, in the US, cold display cases and freezers are meeting safety requirement in light commercial applications; furthermore, propane is gaining acceptance for use in room air-conditioning systems too.

A recent article from the Institute of Refrigeration and Cryogenics, Shanghai Jiao Tong University, Shanghai, China reviews research on R290 condensation and evaporation. 2 According to the authors, this review paper is a starting point for future R290 studies and R290 applications in air conditioning systems.

In an R290 air-conditioner condenser application from Super Radiator Coils, MicroGroove allowed for a reduction in refrigerant charge and maintained high burst pressures with thinner walls. 3 Copper usage was reduced up to 26 percent while increasing capacity up to 6.5 percent as tube diameters were decreased from 9.52 mm (3/8 in.) and 7.94 mm (5/16 in.) to 5 mm; and tube walls were thinned from 0.41 mm (16 mils) and 0.33 mm (13 mils) to 0.25 mm (10 mils), respectively.

In another application from Super Radiator Coils, smaller-diameter (5 mm) copper tubes were used rather than conventional-diameter (9.52 mm) copper tubes in a heat exchanger design for an R290 refrigeration system.
