**GEOLOGICAL PERSPECTIVE**

Typically, the future availability of minerals is based on the concept of reserves and resources. Reserves are deposits that have been discovered, evaluated and assessed to be economically profitable. Resources are far bigger and include reserves, discovered deposits which are potentially profitable, and undiscovered deposits that are predicted based on preliminary geological surveys.

According to the latest science of the United States Geological Survey (USGS), copper reserves amount to 790 million tonnes, and copper resources are currently estimated over 5,000 million tonnes (USGS, 2014 & 2018). The latter does not take into account the vast amounts of copper deposits found in deep sea nodules and submarine massive sulphides. Current and future exploration opportunities will lead to increases in both reserves and known resources; of the around 1,000 copper projects targeted for future exploration, nearly 100 are already under construction (Intierra, 2011).

It is also important to note that copper is naturally present in the Earth’s crust at a concentration of about 28 parts per million (ppm) (Rudnick, 2013). Thus the total resource base of copper is estimated at 300,000 million tonnes (Kesler, 2008). This includes only deposits.

**RESERVES IN CONTRAST TO PRODUCTION**

Since 2000, 290 million tonnes of copper have been mined. In that same period, however, known reserves have grown by 450 million tonnes. As a result, the reserves/mine production ratio has increased by 50% from 26 to 40.

Since 1950 according to USGS data, there has always been, on average, nearly 40 years of copper reserves. This reflects the timeframes, technological advances and evolving economics of mining.

**COPPER IN USE**

Based on the global copper stocks and flows model, recently developed by the Fraunhofer Institute, it is estimated that two-thirds out of the 550 million tonnes of copper produced since 1900 are still in productive use (Glöser, 2013).

Nearly 70 percent of worldwide copper produced is used for electrical applications and communications, as shown in Figure 3.

- Copper has the highest electrical conductivity of any metal, apart from silver. This property makes copper the material of choice to build power grids (45 percent of use)—delivering electricity safely and efficiently to homes and businesses.

---

1 The total amount of copper resources is defined as the sum of undiscovered resources (3,500 million tonnes) and identified resources (2,100 million tonnes) minus the 550 million tonnes of copper mined since 1900.
INVESTING IN TOMORROW: INNOVATION IN MINING AND RECYCLING

Technology has a key role to play in addressing many of the challenges faced by new copper production. Innovation led by the copper industry will:

- increase the success rate in deep exploration and other more difficult areas;
- create safer conditions to operate in extreme environments;
- reduce carbon emissions and water use;
- increase recovery rates in the mill to enable producers to process more complex ores.

These and other innovations will ensure new mine production continues to provide vital copper supplies.

In addition, recycling of copper plays an important role in copper availability. **Today’s primary copper is tomorrow’s recycled material, or secondary copper.** Currently 8.5 million tonnes of copper per year comes from the recycling of “old” scrap (copper contained in end-of-life products) and “new” scrap (scrap generated during production and manufacturing processes). This means that more than 30% of annual copper use comes from recycled sources. More information on copper recycling is available on our main web site.

Unlike other commodities such as energy or food, copper is not “consumed”. Copper is one of the few raw materials that can be recycled repeatedly without any loss of performance. Key players along the copper value chain should work to recycle and reuse the metal. While this will ensure a progressive move towards a more circular economy, the loop cannot be completely closed for two reasons. First, demand will continue to increase due to population growth, product innovation and economic development. Second, in most applications, copper stays in use for decades before being ready to recycle and use again.

Consequently, meeting future metals demand will continue to require a combination of primary raw materials, coming from mines, as well as recycled materials, while innovative policies and technology should continue to contribute to improvements in recycling performance and resource efficiency.

CONCLUSION

Copper is central to providing energy access, improving energy efficiency, and enabling growth in renewable energy sources. Even though copper is civilization’s oldest metal, dating back more than 10,000 years, it continues to play a vital role in addressing issues critical to society.

Based on the latest knowledge on geological availability and continuous industry innovation there are good reasons to believe that copper will continue to be a vital and positive contributor to society well into the future.

DISCLAIMER

This document has been developed to provide information regarding the long-term availability of copper from publically available information. Its purpose is to provide readers with information to make independent business decisions. It contains forward-looking statements based on currently available data. These statements are not guarantees and are subject to risks, uncertainties and other factors.
